

Biodiversity Credits: Direct economic reward for sustainable management

James Shields
Wildlife Manager
State Forests of NSW,
Australia

What is Biodiversity ?

“The sum of all living entities including genetic and species diversity”

“The biodiversity of an ecosystem includes the sum of all living and functional components of the system”

The Biodiversity Dilemma

- Humans consume and develop natural resources at the expense of biodiversity
- Sometimes this leads to environmental collapse (salinity)
- Generally most ecosystems remain functional, however, there are warning signals that most ecosystems are degraded

Biodiversity Resource Allocation

- Currently most resources devoted to biodiversity are channelled to preserve endangered species
- Most biodiversity resources are “owned” by impoverished sectors of society
- Generally this ownership has negative economic consequences

Traditional Agriculture

Biodiversity on your land =

Legislation

NSW Threatened Species Conservation Act
NSW State Environmental Protection Policy
NSW Native Vegetation Act
NSW National Parks and Wildlife Act

Problems

No markets
Competition with domestic stock
Cost of control

Human Impact on Biodiversity

**Some human communities
carry no biodiversity debt,
but most do ...**

Environmental Risk

Some human landscapes are relatively functional and stable

However, environmental collapse can occur ...

THE WEEKEND AUSTRALIAN

NUMBER 11,310 FEBRUARY 3-4 2001 www.news.com.au \$1.90* Includes GST

Murray River pollution reaches its head waters

Fouled from source to sea

FROM the moment it bubbles to the world's surface, Australia's greatest river is polluted by the legacy of human habitation.

The headwaters of the Murray River in New South Wales, contaminated with cryptozoan and plastic, the two bacteria responsible for the 1986 forestry water crisis.

The contamination means there is no longer any clean water about the Murray. From 50 years ago

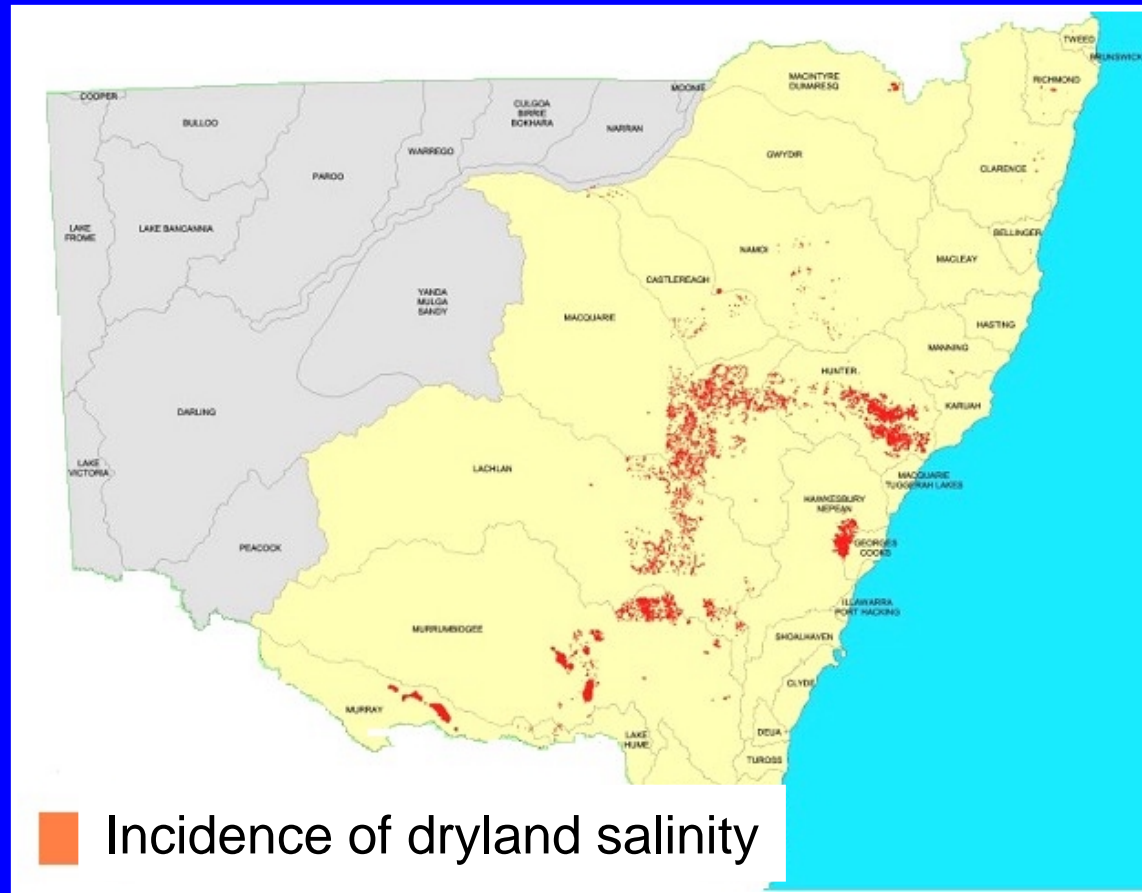

Today The Australian launches a campaign to rescue one of the nation's most cherished environmental treasures, the Murray River. On Monday the newspaper will begin a year of discovery, with environmental reporter Amanda Holden travelling the length of the Murray to profile the river, the communities it supports and the environmental challenges that threaten it. The Australian's journey will culminate in Goolwa in South Australia on February 25.

Dryland Salinity in New South Wales, Australia

6.3 million acres of land currently affected in Australia
Expected to increase to 38 million acres next century

Major Issues

- What measures are required to manage remaining biodiversity resources ?
- How will these measures be financed ?
- How will the social forces and political processes be generated to enact these measures ?

Relevant Parameters

Scope and Scale

Time Scale

Current Solutions

The Drivers

- Few economic or social drivers that will resolve the biodiversity issues
- Social and economic actions will not change in time to deal with ecological management issues due to the temporal and geographic scale of biodiversity management

One Approach

- Measure biodiversity values
- Market these values
- This biodiversity market will drive management to sustainability

Measures of Biodiversity

The BIOS

$$B = EC^r * P * U * 1 / D * C$$

where :

EC^r = Ecological Community (species composition); r is a measure of rarity based on the components therein

P = a productivity measure

U = taxonomic uniqueness

D = distance to next EC

C = condition

Extant Biodiversity

Clearing for traditional agriculture

Management contracts for environmental services (water, air, soil)

The Alternatives

Rehabilitation

Long term decline
in productivity

Example

Camphor Laurel

Native vegetation →

\$\$ credits

Conclusions

- Environmental catastrophes can occur and will cause immediate reaction from society and business.
- Ecological degradation is an essential component of environmental catastrophe.
- Ecological degradation is a large scale problem in spatial and temporal terms.

CONCLUSIONS

- Current resources for ecological management (biodiversity) are small, and directed to listed or charismatic species.
- Giving direct economic reward for positive biodiversity management is one solution.
- Objective measurement of biodiversity values is an essential to implement any system of economic reward for biodiversity.
